

Autonomous Nightly Development Agent

An AI agent that builds, reviews, and reports on the YaysApp project overnight — so work is ready by morning.

Prepared for: Junaid T. | Project: YaysApp (formerly YayChat) | Date: 2026-08-04

In short: a scheduled AI agent starts a development session automatically every night, implements the next planned tasks with Claude Opus, has a second AI (Claude Fable) review and refine the code, produces clean commits and a pull request, and leaves a written daily report. You wake up to reviewed work and a status summary instead of doing it manually.

1. What it is

The agent is an unattended automation running on the local Mac. At a fixed time each night it launches a headless Claude Code session pointed at the YaysApp codebase, follows a written playbook, and drives the full develop → review → commit → report cycle on its own. It requires no one to be present and stops itself when the work is done or its time budget ends.

2. What it does each night

- 1 Loads context.** Reads the current plan (module development plan & timeline), the product PRD, and its own progress ledger to decide what to work on next.
- 2 Selects the next tasks.** Picks the next unblocked items for the current priority module — the Chat MVP — sized to fit the session.
- 3 Implements with Claude Opus.** Writes the code one feature at a time, following the existing patterns and the project's mock-API contracts.
- 4 Reviews with Claude Fable.** After each feature, a separate Claude Fable reviewer checks correctness and production quality, refactors where needed, and the fixes are applied before anything is committed.
- 5 Verifies.** Runs the test suite and linter; it does not commit code that is failing.
- 6 Commits cleanly & opens a PR.** One focused commit per reviewed feature, then a pull request with a clear, well-written description.
- 7 Writes the daily report.** A dated report capturing completed tasks, features, bugs fixed, files changed, review improvements, and remaining work — updated after every feature so it is always current.

3. Why two AI models

Claude Opus — the builder

Does the primary engineering: designs and writes each feature to the plan.

Claude Fable — the reviewer

Independently reviews and refactors each feature for production quality before it is committed.

Separating "build" from "review" gives an independent quality check on every change — the same discipline as a human author-plus-reviewer, applied automatically to every feature.

4. How your effort is reduced

Before (manual)	With the agent (while you sleep)
You implement each feature by hand during the day.	Features are implemented overnight, ready to review in the morning.
Code review is a separate task that competes for your time.	Every feature is already reviewed and refined by a second AI.
You write commit messages, open PRs, and summarize progress.	Clean commits, a written PR, and a daily report are produced for you.
Tracking "what's done vs. left" is manual.	A living progress ledger is maintained automatically.
Progress happens only during working hours.	Progress continues overnight, extending your effective working time.

Net effect: your role shifts from **doing the work** to **reviewing completed, pre-checked work** — a faster, higher-leverage use of your time.

5. Safety & control

- **Fully isolated.** Each run works in a throwaway copy of the latest code; your local, in-progress files are never touched or overwritten.
- **Scoped.** Work is limited to the mobile app area and the current priority module — it will not wander into unrelated code.
- **Reviewed before commit.** Nothing is committed until it passes tests, the linter, and the Fable review.
- **Time-bounded.** Every session has a hard time budget and stops itself; the report is written incrementally so it is useful even if a run is cut short.
- **Local & private.** All output is local files plus the team's own private GitHub repository. Nothing is published to any public or third-party surface.

6. What you get each morning

- A dated **daily report** (completed tasks, features, bugs fixed, files changed, review notes, blockers).
- A **pull request** with reviewed, tested code and a clear description.
- An updated **progress ledger** showing exactly where the project stands.
- A full **session log** if you want the detail.

7. Current status

Item	Status
Nightly schedule installed & armed	Ready Runs automatically each night
Build + review + commit + PR + report pipeline	Ready Configured end to end
Isolation from local work	Verified Confirmed by test
First supervised end-to-end run	Pending To be confirmed today
Real-time chat backend	Blocked Backend build needs a fix before the full Chat MVP can be built; frontend work proceeds meanwhile

The current priority is the **Chat MVP** — real-time messaging between real users — per the module development plan and timeline.
